## PROVISIONAL SPECIFICATION.

No. 19,597, A.D. 1927.

### Improvements in or relating to the Manufacture of Aliphatic Acid Anhydrides.

We, BRITISH CELANESE LIMITED, of 8, Waterloo Place, London, S.W. 1, a company incorporated in accordance with the laws of Great Britain, HENRY DREYFUS, 5 of 8, Waterloo Place, London, S.W. 1, a citizen of the Swiss Republic, and WALTER BADER, of the Works of British Celanese Limited, Spondon, near Derby, a citizen of the Swiss Republic, do hereby 10 declare the nature of this invention to be as follows :—

This invention relates to the manufacture of anhydrides of aliphatic acids and especially to the manufacture of acetic 15 anhydride.

According to the invention we have now found that aliphatic anhydrides (and especially acetic anhydride) can be satisfactorily produced by treating liquid 20 aliphatic acids and/or metal salts of aliphatic acids with salts of phosphoric acids of lower degree of hydration than orthophosphoric acid, as for instance with one or more alkali or alkali earth salts 25 of a metaphosphoric acid or pyrophosphoric acid.

According to one form of execution of

the invention we may mix acetic acid, preferably glacial acetic acid (in presence or absence of acetic anhydride), with a sodium salt of a metaphosphoric acid, the reaction being accelerated by heating or preferably by boiling the mixture. By this means a high yield of acetic anhydride may be readily produced, the anhydride being separated from the reaction mixture, for instance by distillation or by filtration with or without subsequent distillation.

According to the relative proportions of metaphosphate and acetic acid employed acid sodium pyrophosphate or acid sodium orthophosphate are produced with the acetic anhydride. For instance when substantially equimolecular proportions of acetic acid and of the metaphosphate (reckoned as  $\text{NaPO}_3$ ) are employed the residue consists largely or mainly of acid sodium pyrophosphate, whereas if about two molecular equivalents of acetic acid 40 are employed the residue consists largely or mainly of acid sodium orthophosphate; 45 in these cases the reactions probably proceed according to the equations :—

In order to utilise the dehydrating capacity of the metaphosphate to the full we preferably use sufficient acetic acid to transform the metaphosphate to acid sodium orthophosphate, e.g. about 2 molecules of acetic acid for each molecule of 60 metaphosphate (reckoned as  $\text{NaPO}_3$ ). By using excess of acetic acid (i.e. an excess over the 2 molecules) mixtures of acetic acid and acetic anhydride may be obtained which are highly useful for 65 industrial acetylation processes such for instance as the manufacture of cellulose acetate.

When the residue contains acid sodium pyrophosphate it may, with or without

separation of the acetic anhydride, be 75 employed for reaction with further acetic acid to produce further acetic anhydride. For instance a further molecular proportion of acetic acid (or if desired an excess of acetic acid) may be 80 added to the residue and the mixture again heated or boiled and the anhydride so produced recovered as above described.

The residues from the reactions (whether such residues consist substantially of acid orthophosphate or acid pyrophosphate or of mixtures of such phosphates) may readily be transformed into 85 metaphosphate which may be made to 90

[Price 1/-]

serve for treating fresh quantities of acetic acid, and thus the process may be conducted as a continuous cycle of operations. For instance the residues may be heated, in a manner known for the production of metaphosphates from acid orthophosphates or acid pyrophosphates, and the metaphosphate so produced treated with fresh acetic acid in the manner above described; or when the residues consist substantially of acid orthophosphate they may if desired be heated to form acid pyrophosphate instead of metaphosphate, which acid pyrophosphate may similarly be treated with fresh acetic acid.

According to another form of execution of the invention we may employ a metal acetate, for instance an alkali or alkali earth acetate, instead of acetic acid. The acetates are preferably employed in their anhydrous form.

In such form of execution we may for example melt sodium acetate with a sodium salt of a metaphosphoric acid and separate the anhydride by distillation or by filtration with or without subsequent distillation.

Preferably however we perform the

In order to utilise the dehydrating capacity of the metaphosphate to the full we preferably use sufficient sodium acetate to transform the metaphosphate to the neutral (trisodium) orthophosphate.

When the residue from the reaction contains neutral sodium pyrophosphate it may, with or without separation of the acetic anhydride, be employed to react with further quantities of sodium acetate or with acetic acid. For instance a further molecular equivalent of sodium acetate may be added to the residue and the mixture heated, or preferably boiled after dilution with acetic anhydride, and the acetic anhydride so produced recovered as above described.

Where the residues consist largely or mainly of neutral pyrophosphate or of neutral orthophosphate they may be recovered as metaphosphate or as neutral pyrophosphate by suitable treatment after acidification (preferably with acetic acid) and the process thus made a continuous cycle of operations. For instance, when the residues consist largely or mainly of neutral (trisodium) orthophosphate, it may be mixed with about one molecular equivalent of aqueous acetic acid whereby a mixture of disodium hydrogen phosphate and sodium acetate may be pro-

reaction in presence of a non-aqueous diluent, such for example as acetic anhydride. For instance, we may heat, or preferably boil, a mixture of a sodium metaphosphate and sodium acetate with acetic anhydride and recover the acetic anhydride so produced by distillation or by filtration with or without subsequent distillation. By these means highly satisfactory yields of acetic anhydride may be obtained.

According to relative proportions of metaphosphate and acetate employed neutral pyrophosphate or neutral (trisodium) orthophosphate are produced together with the anhydride. Thus for instance, when substantially equimolecular proportions of the metaphosphate (reckoned as  $\text{NaPO}_3$ ) and sodium acetate are employed the residue consists largely or mainly of neutral sodium pyrophosphate, whereas, if about two molecular equivalents of sodium acetate are employed the residue consists largely or mainly of neutral (trisodium) orthophosphate, in these cases the reactions probably proceed according to the equations:—

duced. This mixture may be evaporated to dryness, and by further heating (preferably under reduced pressure) transformed into a mixture of sodium pyrophosphate and sodium acetate. This resulting mixture may be heated, or preferably boiled with a suitable non-aqueous solvent, such for instance as acetic anhydride, to produce further acetic anhydride.

Or for instance when the residue consists largely or mainly of neutral (trisodium) orthophosphate or of neutral sodium pyrophosphate, the residue may be treated with acids in known manner to produce disodium hydrogen phosphate ( $\text{Na}_2\text{HPO}_4$ ). This may then be treated with aqueous acetic acid and ammonia to produce a mixture of acid sodium ammonium phosphate (microcosmic salt) and sodium acetate which may be separated by fractional crystallisation, for instance by cooling the solution at suitable concentration whereby the acid sodium ammonium phosphate is largely or entirely precipitated and the sodium acetate remains in solution. The separated sodium ammonium phosphate may then be heated to produce sodium metaphosphate which may then be treated with fresh acetic acid or sodium acetate to produce further

acetic anhydride. The sodium acetate separated from the acid sodium ammonium phosphate may be recovered from the solution and utilised for the production of 5 acetic anhydride by the process of the invention. The ammonia liberated on heating the acid sodium ammonium phosphate may be used for treating disodium hydrogen phosphate (and especially 10 disodium hydrogen phosphate prepared as described above) to produce further quantities of sodium ammonium phosphate for use in the process.

It will thus be seen that the utilisation 15 of the residues and the execution of the process as a continuous cycle of operations though somewhat more complicated when salts of acetic acid are employed instead of acetic acid, still enables very efficient 20 recovery and utilisation of the reagents.

It will be understood that the above forms of execution of the invention are given only by way of illustration and are in no way limitative.

25 Instead of sodium acetate we may employ potassium acetate or other alkali or earth alkali or other metal acetate.

Further we may employ mixtures of 30 sodium acetate or other alkali or earth alkali or other metal acetate with acetic acid.

When employing mixtures of acetates and acetic acid we preferably employ excess acetic acid to act as diluent for the reaction. For instance we may heat, or 35 preferably boil, a mixture of sodium acetate and a sodium metaphosphate (or pyrophosphate) after dilution with glacial acetic acid or after dilution with a mixture of acetic acid and acetic anhydride, and recover the acetic anhydride so produced by distillation or by filtration with or without subsequent distillation.

In performing the invention with 40 acetates or mixtures thereof and acetic acid, the acetates should preferably be employed in their anhydrous form.

Instead of acetic acid or acetates we 45 may employ any other aliphatic acids or sodium or other alkali or alkali earth or other metal salts of such acids.

Instead of sodium salts of phosphoric acids of lower degree of hydration than orthophosphoric acid we may employ 50 potassium or any other salts (including acid salts) of such acids.

Dated this 23rd day of July, 1927.

#### PROVISIONAL SPECIFICATION.

No. 19,598, A.D. 1927.

#### Improvements in or relating to the Manufacture of Aliphatic Acid Anhydrides.

We, BRITISH CELANESE LIMITED, of 8, Waterloo Place, London, S.W. 1, a company incorporated in accordance with the laws of Great Britain, HENRY DREYFUS, of 8, Waterloo Place, London, S.W. 1, and WALTER BADER, of the Works of British Celanese Limited, Spondon, near Derby, both citizens of the Swiss Republic, do hereby declare the nature of 65 this invention to be as follows:—

This invention relates to the manufacture of anhydrides of aliphatic acids and especially to the manufacture of acetic 70 anhydride.

According to the invention we have now found that aliphatic anhydrides (and especially acetic anhydride) can be satisfactorily produced by treating liquid 75 aliphatic acids and/or metal salts of aliphatic acids with one or more phosphoric acids of lower degree of hydration than orthophosphoric acid.

In performing the invention we may 80 for instance mix acetic acid, preferably

glacial acetic acid (in presence or absence of acetic anhydride) with a metaphosphoric acid and heat, or preferably boil, the mixture to accelerate the reaction. By this means acetic anhydride may 85 readily be produced, the anhydride being separated from the reaction mixture, for instance by distillation.

According to the relative proportions of the metaphosphoric acid and the acetic acid employed pyrophosphoric acid or orthophosphoric acid are produced with the anhydride. For instance when substantially equimolecular proportions of acetic acid and metaphosphoric acid (reckoned as  $HPO_3$ ) are employed the metaphosphoric acid is transformed largely or entirely to pyrophosphoric acid, whereas if about 2 molecular equivalents of acetic acid are employed 95 metaphosphoric acid is transformed largely or entirely to orthophosphoric acid; in these cases the reactions probably 100 proceed according to the equations:

5 In order to utilise the dehydrating capacity of the metaphosphoric acid to the full we preferably use sufficient acetic acid to transform metaphosphoric acid to orthophosphoric acid e.g. about two molecules of acetic acid for each molecule of metaphosphoric acid (reckoned as  $\text{HPO}_3$ ).  
 10 By using excess acetic acid (i.e. excess over the 2 molecules) mixtures of acetic acid and acetic anhydride may be obtained which are highly useful for industrial acetylation processes such for instance as the manufacture of cellulose acetate.

20 When the residue from the reaction contains pyrophosphoric acid it may, with or without separation of the acetic anhydride, be employed for reaction with further acetic acid to produce further acetic anhydride. For instance a further molecular proportion of acetic acid (or if desired an excess of acetic acid) may be added to the residue and the mixture again heated or boiled and the anhydride so produced recovered as above described.

30 The residues from the reactions (whether such residues consist substantially of orthophosphoric acid or of pyrophosphoric acid or of mixtures of such acids) may readily be transformed into a metaphosphoric acid, which may be made to serve for treating fresh quantities of acetic acid, and thus the process may be conducted as a continuous cycle of operations. For instance the residues may be heated, in the manner known for the production of metaphosphoric acids from orthophosphoric acid or pyrophosphoric acid, and the metaphosphoric acid so produced treated with fresh acetic acid in the manner above described: or when the residues consist substantially of ortho-

phosphoric acid they may if desired be heated to form pyrophosphoric acid instead of metaphosphoric acid, which pyrophosphoric acid may similarly be 50 treated with fresh acetic acid.

According to another and more preferable form of execution of the invention we may employ a metal acetate, for instance an alkali or earth alkali acetate, instead 55 of acetic acid.

In such form of execution we may for example heat a mixture of sodium acetate and a metaphosphoric acid and separate the anhydride by distillation. Preferably however we perform the reaction in presence of a non-aqueous diluent, such for instance as acetic anhydride. For instance we may heat, or preferably boil, a mixture of a metaphosphoric acid and sodium acetate with acetic anhydride and recover the acetic anhydride so produced by distillation or by filtration with or without subsequent distillation. By these means highly satisfactory yields of acetic 60 anhydride may be obtained.

According to the relative proportions of the metaphosphoric acid and the acetate employed acid sodium pyrophosphate or disodium hydrogen phosphate are produced together with the anhydride. Thus, for instance, when substantially equimolecular proportions of the metaphosphoric acid (reckoned as  $\text{HPO}_3$ ) and sodium acetate are employed the residue consists 75 largely or mainly of acid sodium pyrophosphate, whereas if about 2 molecular equivalents of sodium acetate are employed the residue consists largely or mainly of disodium hydrogen phosphate, 80 in these cases the reactions probably proceed according to the equations:

95 In order to utilise the dehydrating capacity of the metaphosphoric acid to the full we preferably use sufficient acetate to transform the metaphosphoric acid to disodium hydrogen phosphate.

100 When the residue from the reaction contains acid sodium pyrophosphate it may, with or without separation of the acetic anhydride, be employed to react with further quantities of sodium acetate or with acetic acid. For instance a further molecular equivalent of sodium acetate may be added and the mixture

heated, or preferably boiled, after dilution with acetic anhydride, and the acetic anhydride so produced recovered as above described.

105 Where the residues consist largely or mainly of acid sodium pyrophosphate or disodium hydrogen phosphate they may be recovered as metaphosphoric acid or pyrophosphoric acid by a suitable treatment, and thus the process may be conducted as a continuous cycle of operations. 110 For instance when the residue consists largely or mainly of disodium hydrogen 115

phosphate it may be acidified in known manner to produce orthophosphoric acid which may be heated to produce a meta-phosphoric acid or pyrophosphoric acid 5 which may then be treated with fresh acetic acid or sodium acetate to produce further acetic anhydride. Or, for instance, when the residue consists largely or mainly of acid sodium pyro-phosphate it may be treated with acids in known manner to produce an orthophosphate. This may then be treated with acids in known manner to produce ortho-phosphoric acid which may be heated to 10 produce a metaphosphoric acid or a pyro-phosphoric acid which may then be treated with fresh acetic acid or sodium acetate to produce further acetic anhydride. 15

20 Or, if desired the residue from the reaction may be heated in known manner to produce a sodium metaphosphate or pyro-phosphate which may be employed for the execution of the process of our co-pending

25 Application No. 19,597/27 of even date herewith. It will be understood that the above forms of execution of the invention are given only by way of illustration and are in no way limitative.

30 Instead of sodium acetate we may employ potassium acetate or other alkali

or earth alkali or other metal acetate. Further we may employ mixtures of sodium acetate or other alkali or other metal acetate with acetic acid. 35

When employing mixtures of acetates and acetic acid we preferably employ excess acetic acid to act as diluent for the reaction. For instance we may heat, or preferably boil, a mixture of sodium acetate with a metaphosphoric acid after dilution with glacial acetic acid or after dilution with a mixture of acetic anhydride and acetic acid, and recover the anhydride so produced, by distillation 40 or by filtration with or without subsequent distillation. 45

In performing the invention with acetates or mixtures thereof with acetic acid, the acetates should preferably be employed in their anhydrous form. 50

Instead of acetic acid or acetates we may employ any other aliphatic acids or sodium or other alkali or alkali earth or other metal salts of such acids. 55

#### COMPLETE SPECIFICATION.

#### Improvements in or relating to the Manufacture of Aliphatic Acid Anhydrides.

We, BRITISH CELANESE LIMITED, of 8, Waterloo Place, London, S.W. 1, a company incorporated in accordance with the laws of Great Britain, HENRY DREYFUS, 60 of 8, Waterloo Place, London, S.W. 1, a citizen of the Swiss Republic, and WALTER BADER, of the Works of British Celanese Limited, Spondon, near Derby, a citizen of the Swiss Republic, do hereby declare the nature of this invention and in what manner the same is to be performed, to be particularly described and ascertained in and by the following statement:—

70 This invention relates to the manufacture of anhydrides of aliphatic acids and especially to the manufacture of acetic anhydride.

In previous Specification No. 280,972 75 Henry Dreyfus has described how phosphoric acids may be employed as catalysts in the formation of acetic anhydride by the thermal decomposition of acetic acid.

80 According to the present invention we have now found that aliphatic anhydrides

(and especially acetic anhydride) can be satisfactorily produced by treating liquid aliphatic acids and/or metal salts of aliphatic acids with phosphoric acids of lower degree of hydration than orthophosphoric acid and/or salts of such phosphoric acids (as for instance with metaphosphoric acid or pyrophosphoric acid or with alkali or earth alkali salts of metaphosphoric or pyrophosphoric acid). 85

According to one form of execution of the invention we may mix acetic acid, preferably glacial acetic acid (in presence or absence of acetic anhydride), with a sodium salt of a metaphosphoric acid, the reaction being accelerated by heating or preferably boiling the mixture. By this means a high yield of acetic anhydride 90 may be readily produced, the anhydride being separated from the reaction mixture, for instance, by distillation or by filtration with or without subsequent distillation. 95

According to the relative proportions of 100 metaphosphate and acetic acid employed acid sodium pyrophosphate or acid sodium

orthophosphate are produced with the acetic anhydride. For instance when substantially equimolecular proportions of acetic acid and of the metaphosphate (reckoned as  $\text{NaPO}_3$ ) are employed the residue consists largely or mainly of acid

sodium pyrophosphate, whereas if about two molecular equivalents of acetic acid are employed the residue consists largely or mainly of acid sodium orthophosphate; 10 in these cases the reactions probably proceed according to the equations:—

acid sodium orthophosphate.

In order to utilise the dehydrating capacity of the metaphosphate to the full we preferably use sufficient acetic acid to 20 transform the metaphosphate to acid sodium orthophosphate, e.g. about 2 molecules of acetic acid for each molecule of metaphosphate (reckoned as  $\text{NaPO}_3$ ). By 25 using excess of acetic acid (i.e. an excess over the 2 molecules) mixtures of acetic acid and acetic anhydride may be obtained which are highly useful for 30 industrial acetylation processes such for instance as the manufacture of cellulose acetate.

When the residue contains acid sodium 35 pyrophosphate it may, with or without separation of the acetic anhydride, be employed for reaction with further acetic acid to produce further acetic anhydride. For instance a further molecular proportion of acetic acid (or if desired an excess of acetic acid) may be 40 added to the residue and the mixture again heated or boiled and the anhydride so produced recovered as above described.

The residues from the reactions 45 (whether such residues consist substantially of acid orthophosphate or acid pyrophosphate or of mixtures of such phosphates) may readily be transformed into metaphosphate which may be made to serve for treating fresh quantities of acetic acid, and thus the process may be 50 conducted as a continuous cycle of operations. For instance the residues may be heated, in a manner known for the production of metaphosphates from acid orthophosphates or acid pyrophosphates, 55 and the metaphosphate so produced treated with fresh acetic acid in the manner above described; or when the residues consist substantially of acid orthophosphate they may if desired be 60 heated to form acid pyrophosphate

instead of metaphosphate, which acid pyrophosphate may similarly be treated with fresh acetic acid.

According to another form of execution of the invention we may employ a metal acetate, for instance an alkali or alkali earth acetate, instead of acetic acid. The acetates are preferably employed in their anhydrous form.

70 In such form of execution we may for example melt sodium acetate with a sodium salt of a metaphosphoric acid and separate the anhydride by distillation or by filtration with or without subsequent distillation.

75 Preferably however we perform the reaction in presence of a non-aqueous diluent, such for example as acetic anhydride. For instance, we may heat, or preferably boil, a mixture of a sodium metaphosphate and sodium acetate with acetic anhydride and recover the acetic anhydride so produced by distillation or by filtration with or without subsequent distillation. By these means highly satisfactory yields of acetic anhydride may be obtained.

80 According to relative proportions of metaphosphate and acetate employed neutral pyrophosphate or neutral (trisodium orthophosphate are produced together with the anhydride. Thus, for 85 instance, when substantially equimolecular proportions of the metaphosphate (reckoned as  $\text{NaPO}_3$ ) and sodium acetate are employed the residue consists largely or mainly of neutral sodium pyrophosphate, whereas, if about two molecular equivalents of sodium acetate are 90 employed the residue consists largely or mainly of neutral (trisodium) orthophosphate, in these cases the reactions 95 probably proceed according to the equations:—

neutral sodium pyrophosphate

neutral (trisodium) orthophosphate.

In order to utilise the dehydrating 110 capacity of the metaphosphate to the full we preferably use sufficient sodium acetate to transform the metaphosphate to the neutral (trisodium) orthophosphate.

When the residue from the reaction 115 contains neutral sodium pyrophosphate it may, with or without separation of the acetic anhydride, be employed to react with further quantities of sodium acetate

or with acetic acid. For instance a further molecular equivalent of sodium acetate may be added to the residue and the mixture heated, or preferably boiled 5 after dilution with acetic anhydride, and the acetic anhydride so produced recovered as above described.

Where the residues consist largely or mainly of neutral pyrophosphate or of 10 neutral orthophosphate they may be recovered as meaphosphate or as neutral pyrophosphate by suitable treatment after acidification (preferably with acetic acid) and the process thus made a continuous 15 cycle of operations. For instance, when the residues consist largely or mainly of neutral (trisodium) orthophosphate, it may be mixed with about one molecular equivalent of aqueous acetic acid where- 20 by a mixture of disodium hydrogen phosphate and sodium acetate may be pro- 25 duced. This mixture may be evaporated to dryness, and by further heating (preferably under reduced pressure) trans- 30 formed into a mixture of sodium pyro- phosphate and sodium acetate. This resulting mixture may be heated, or preferably boiled with a suitable non- aqueous solvent, such for instance as acetic anhydride, to produce further acetic anhydride.

Or for instance when the residue consists largely or mainly of neutral (trisodium) orthophosphate or of neutral 35 sodium pyrophosphate, the residue may be treated with acids in known manner to produce disodium hydrogen phosphate ( $Na_2HPO_4$ ). This may then be treated with aqueous acetic acid and ammonia to pro- 40 duce a mixture of sodium ammonium phosphate (microcosmic salt) and sodium acetate which may be separated by frac- 45 tional crystallisation, for instance, by cooling the solution at suitable concen- tration whereby the sodium ammonium phosphate is largely or entirely pre- 50 precipitated and the sodium acetate remains in solution. The separated sodium ammonium phosphate may then be heated to produce sodium meta- 55 phosphate which may then be treated with fresh acetic acid or sodium acetate to pro- 60 duce further acetic anhydride. The sodium acetate separated from the sodium ammonium phosphate may be recovered from the solution and utilised for the pro- 65 duction of acetic anhydride by the process of the invention. The ammonia liber- ated on heating the sodium ammonium phosphate may be used for treating disodium hydrogen phosphate (and especially disodium hydrogen phosphate prepared as described above) to produce further quantities of sodium ammonium phosphate for use in the process.

It will thus be seen that the utilisation of the residues and the execution of the process as a continuous cycle of operations though somewhat more complicated when salts of acetic acid are employed instead of acetic acid, still enables very efficient recovery and utilisation of the re- 70 agents.

It will be understood that the above 75 forms of execution of the invention are given only by way of illustration and are in no way limitative.

Instead of sodium acetate we may 80 employ potassium acetate or other alkali or earth alkali or other metal acetate.

Further we may employ mixtures of 85 sodium acetate or other alkali or earth alkali or other metal acetate with acetic acid.

When employing mixtures of acetates and acetic acid we preferably employ excess acetic acid to act as diluent for the reaction. For instance we may heat, or 90 preferably boil, a mixture of sodium acetate and a sodium metaphosphate (or pyrophosphate) after dilution with glacial acetic acid or after dilution with a mixture of acetic acid and acetic anhydride, and recover the acetic anhydride so produced by distillation or by filtration with 95 or without subsequent distillation.

Instead of acetic acid or acetates we 100 may employ any other aliphatic acids or sodium or other alkali or alkali earth or other metals salts of such acids.

Instead of sodium salts of phosphoric acids of lower degree of hydration than orthophosphoric acid we may employ potassium or any other salts (including acid salts) of such acids.

According to another form of execution 105 of the invention we may for instance mix acetic acid, preferably glacial acetic acid (in presence or absence of acetic anhydride) with a metaphosphoric acid and heat, or preferably boil, the mixture to accelerate the reaction. By this means 110 acetic anhydride may readily be produced, the anhydride being separated from the reaction mixture, for instance, 115 by distillation.

According to the relative proportions of 120 the metaphosphoric acid and the acetic acid employed pyrophosphoric acid or orthophosphoric acid are produced with the anhydride. For instance when sub- 125 stantially equimolecular proportions of acetic acid and metaphosphoric acid (reckoned as  $HPO_3$ ) are employed the metaphosphoric acid is transformed largely or entirely to pyrophosphoric acid, whereas if about 2 molecular equivalents of acetic acid are employed metaphosphoric acid is transformed largely or entirely to orthophosphoric acid; in these 130

cases the reactions probably proceed according to the equations :—

5

In order to utilise the dehydrating capacity of the metaphosphoric acid to the full we preferably use sufficient acetic acid to transform metaphosphoric acid to orthophosphoric acid e.g. about two molecules of acetic acid for each molecule of metaphosphoric acid (reckoned as  $\text{HPO}_3$ ). By using excess acetic acid (i.e. excess over the 2 molecules) mixtures of acetic acid and acetic anhydride may be obtained which are highly useful for industrial acetylation processes such for instance as the manufacture of cellulose acetate.

When the residue from the reaction contains pyrophosphoric acid it may, with or without separation of the acetic anhydride be employed for reaction with further acetic acid to produce further acetic anhydride. For instance, a further molecular proportion of acetic acid (or, if desired, an excess of acetic acid) may be added to the residue and the mixture again heated or boiled and the anhydride so produced recovered as above described.

The residues from the reactions (whether such residues consist substantially of orthophosphoric acid or of pyrophosphoric acid or of mixtures of such acids) may readily be transformed into a metaphosphoric acid, which may be made to serve for treating fresh quantities of acetic acid, and thus the process may be conducted as a continuous cycle of operations. For instance the residues may be heated, in the manner known for the production of metaphosphoric acids from orthophosphoric acid or pyrophosphoric acid, and the metaphosphoric acid so produced treated with fresh acetic acid in the manner above described; or when the residues consist substantially of ortho-

phosphoric acid they may if desired be heated to form pyrophosphoric acid instead of metaphosphoric acid, which pyrophosphoric acid may similarly be treated with fresh acetic acid.

According to another and more preferable form of execution of the invention we may employ a metal acetate, for instance, an alkali or earth alkali acetate, instead of acetic acid.

In such form of execution we may, for example, heat a mixture of sodium acetate and a metaphosphoric acid and separate the anhydride by distillation. Preferably, however, we perform the reaction in presence of a non-aqueous diluent, such for instance as acetic anhydride. For instance, we may heat, or preferably boil, a mixture of a metaphosphoric acid and sodium acetate with acetic anhydride and recover the acetic anhydride so produced by distillation or by filtration with or without subsequent distillation. By these means highly satisfactory yields of acetic anhydride may be obtained.

According to the relative proportions of the metaphosphoric acid and the acetate employed acid sodium pyrophosphate or disodium hydrogen phosphate are produced together with the anhydride. Thus for instance, when substantially equimolecular proportions of the metaphosphoric acid (reckoned as  $\text{HPO}_3$ ) and sodium acetate are employed the residue consists largely or mainly of acid sodium pyrophosphate, whereas if about 2 molecular equivalents of sodium acetate are employed the residue consists largely or mainly of disodium hydrogen phosphate, in these cases the reactions probably proceed according to the equations :—

In order to utilise the dehydrating capacity of the metaphosphoric acid to the full we preferably use sufficient acetate to transform the metaphosphoric acid to disodium hydrogen phosphate.

When the residue from the reaction contains acid sodium pyrophosphate it may, with or without separation of the acetic anhydride, be employed to react with further quantities of sodium acetate or with acetic acid. For instance, a further molecular equivalent of sodium

acetate may be added and the mixture heated, or preferably boiled, after dilution with acetic anhydride, and the acetic anhydride so produced recovered as above described.

Where the residues consist largely or mainly of acid sodium pyrophosphate or disodium hydrogen phosphate they may be recovered as metaphosphoric acid or pyrophosphoric acid by a suitable treatment, and thus the process may be conducted as a continuous cycle of operations. For

instance, when the residue consists largely or mainly of disodium hydrogen phosphate it may be acidified in known manner to produce orthophosphoric acid which may be heated to produce a metaphosphoric acid or pyrophosphoric acid which may then be treated with fresh acetic acid or sodium acetate to produce further acetic anhydride. Or, for instance, when the residue consists largely or mainly of acid sodium pyrophosphate it may be treated with acids in known manner to produce an orthophosphate. This may then be treated with acids in known manner to produce orthophosphoric acid which may be heated to produce a metaphosphoric acid or a pyrophosphoric acid which may then be treated with fresh acetic acid or sodium acetate to produce further acetic anhydride.

Or, if desired, the residue from the reaction may be heated in known manner to produce a sodium metaphosphate or pyrophosphate which may be employed for the production of further quantities of anhydride in the manner hereinbefore indicated. It will be understood that the above forms of execution of the invention are given only by way of illustration and are in no way limitative.

Instead of sodium acetate we may employ potassium acetate or other alkali or earth alkali or other metal acetate.

Further we may employ mixtures of sodium acetate or other alkali or other metal acetate with acetic acid.

When employing mixtures of acetates and acetic acid we preferably employ excess acetic acid to act as diluent for the reaction. For instance, we may heat or preferably boil, a mixture of sodium acetate with a metaphosphoric acid after dilution with glacial acetic acid or after dilution with a mixture of acetic anhydride and acetic acid, and recover the anhydride so produced, by distillation or by filtration with or without subsequent distillation.

In performing the invention with acetates or mixtures thereof with acetic acid, the acetates should preferably be employed in their anhydrous form.

Instead of acetic acid or acetates we may employ any other aliphatic acids or sodium or other alkali or alkali earth or other metal salts of such acids.

In performing the invention we may, as hereinbefore indicated, heat or boil the various reaction mixtures to accelerate the formation of the anhydride. Whilst such reaction mixtures may be heated or boiled in any suitable manner, the best results appear to be obtained when the heating or boiling is performed at temperatures of between about 100° and

250° C, and especially at temperatures of from about 120° and 180° C. In cases where acetic or other aliphatic acid is caused to react with the said phosphoric acid (and/or phosphate) and where the boiling point of the said aliphatic acid is not sufficiently raised by admixture with the phosphoric acid (and/or phosphate) to enable the reaction mixture to be boiled at the desired temperature, the boiling may of course be performed under increased pressure, pressures of up to 3 atmospheres usually sufficing for this purpose.

In cases where salts (i.e. either salts of aliphatic acids or salts of said phosphoric acids or salts of both of such acids) are employed for producing the anhydride it is often advantageous to mix indifferent powders, such for instance as kieselguhr or infusorial earth with the reaction mixtures, such admixing serving in many cases to prevent caking.

It will of course be understood that in cases where the anhydride is distilled from the reaction mixtures, such distillation may be effected under any desired pressure, e.g. under normal atmospheric pressure or under reduced pressure. Further, if desired, such distillation may be aided by blowing air, carbon dioxide or other indifferent gas through the reaction vessel.

The following examples serve to illustrate one form of execution of the invention, it being understood that these are given only by way of illustration and in no way as limitative.

#### EXAMPLE 1.

100 lbs. of sodium metaphosphate in the form of a fine dry powder is mixed with 150 lbs. of anhydrous powdered sodium acetate and 20 lbs. of dry infusorial earth. The resulting mixture is stirred in a pan and heated to about 150° C. The pan is closed and connected with a condenser and receiver. Glacial acetic acid is slowly and continuously added to the mixture at such speed that the mixture appears just moist. The heating and addition of acetic acid are maintained so long as acetic anhydride appears in the distillate, then the acetic acid supply is cut off and the residue distilled dry. The residue remaining after distillation is composed substantially of trisodium orthophosphate whilst the distillate is composed substantially of 85 to 90 lbs. of acetic anhydride and about 350 lbs. of glacial acetic acid.

#### EXAMPLE 2.

A mixture of 100 parts of sodium metaphosphate (in the form of a fine dry powder), 150 parts of anhydrous powdered sodium acetate and 20 parts of dry

infusorial earth is caused to pass in any suitable and continuous manner into and through a reaction vessel heated to about 150° to 180° C., the vessel being provided 5 with a condenser and receiver. In its passage through the reaction vessel glacial acetic acid in liquid form is added to the powder at one or more places along the path of the powder, the addition of acetic acid being such as to keep the powder just moist. The acetic anhydride so formed 10 passes, with acetic acid, to the receiver and condenser; whilst the powder is caused to pass continuously from the 15 reaction vessel. By such means acetic anhydride may readily be produced and by regulating the passage of the reaction powder the sodium metaphosphate may be decomposed substantially entirely to tri- 20 sodium orthophosphate.

Having now particularly described and ascertained the nature of our said invention and in what manner the same is to be performed, we declare that what we 25 claim is:—

1. Process for the manufacture of aliphatic anhydrides (and especially acetic anhydride) characterised in that liquid aliphatic acids and/or metal salts 30 of such acids are caused to react with phosphoric acids of lower degree of hydration than orthophosphoric acid and/or with salts of such phosphoric acids.

2. Process according to Claim 1 and 35 wherein the reaction is performed by heating an alkali, earth alkali or other metal salt of acetic or other aliphatic acid with an alkali or earth alkali salt of metaphosphoric acid or of pyrophosphoric acid in presence or absence of a non-aqueous 40 diluent.

3. Process according to Claim 1 or 2 and wherein sufficient aliphatic acid (or salt thereof) is employed in the reaction mass to hydrate the phosphoric acid (or phosphate) substantially to orthophosphoric acid (or orthophosphate). 45

4. Process according to Claim 3, and wherein the reaction is performed by heating one molecular equivalent of metaphosphoric acid or of sodium or other metaphosphate with about two molecular equivalents of acetic acid or of sodium or other alkali acetate. 50

5. Process according to Claim 1, 2, 3 or 4 and wherein the reaction is performed at temperatures of from about 100° to 250° C. and preferably at temperatures of from about 150° to 180° C. 55

6. Process according to Claim 1, 2, 3, 4 or 5, and wherein the process is performed as a continuous cycle of operations, the residues from the reaction, after treatment by any of the methods hereinbefore described for regenerating the said phosphoric acids or salts thereof, being caused to react with further quantities of the aliphatic acids or salts thereof. 65

7. Process for the manufacture of acetic anhydride substantially as described in Example 1 or Example 2.

8. Process for the manufacture of acetic or other aliphatic anhydrides substantially as hereinbefore described. 70
